# Physics I (Spring 2023): Midterm Examination 

Apr. 21, 2023
[total 25 pts, closed book, 90 minutes]

- First, make sure you have all 6 answer sheets. Write down your name and student ID on each of all 6 answer sheets. Then, number the sheets from (1) to (6) on the top right corner. Your answer to each problem must only be in the sheet with the matching number (e.g., your answer to Problem 2 must only be in sheet (2)). After the exam, you will separately turn in all 6 answer sheets, even if some sheets are still blank.
- Make sure you have all 6 problems. Have a quick look through them all and portion your time wisely. If you have any issue or question on the problem itself or on English expressions, you must raise it in the first 45 minutes. You have to stay in the room for that 45 minutes even if you have nothing to write down.
- Exhibit all intermediate steps to receive full credits. Make your writing easy to read. Illegible answers will not be graded. You are welcomed to use a scientific calculator - physical one or the one on your cellphone. Obtain numerical results accurate to two significant figures.
- Gravitational acceleration $g=9.8 \mathrm{~m} / \mathrm{s}^{2}$. Assume negligible friction and air resistance, unless stated otherwise. Any cord connecting one object to another is massless, unless stated otherwise.

1. (a) [2 pt] A firefighter uses a water cannon to fill a cylindrical storage tank of radius $R=2.0$ m and height $H=6.0 \mathrm{~m}$, with its top fully open. The cannon is located $D=18.0 \mathrm{~m}$ away from the tank (see figure), and the water is shot at angle $\theta=45^{\circ}$ above the horizontal from the same level as the base of the tank. For what range of launch speeds $v_{0}$ will the water enter the tank?

(b) [2 pt] A professional clown attempts to get laughs with classic slapstick comedy. He is about to pull a rope vertically downward that passes around three pulleys and is then tied around his ankle (see figure). The clown weighs $m=75 \mathrm{~kg}$, and the coefficient of static friction between
the clown's feet and the ground is $\mu_{s}=0.52$. Each pulley has negligible mass and negligible friction on its axle. What is the minimum force magnitude $T$ that the clown must pull with in order to yank his feet out from under himself?

2. (a) [2 pt] A steel ball of mass $m=3.0 \mathrm{~kg}$ and negligible size is attached to two points ( $A$ and $B$ ) of a massless vertical rod by means of two massless strings of the same lengths $l=2.5 \mathrm{~m}$. Point A and B are 3.0 m apart (see figure), and the whole system rotates about the axis of the rod at a constant angular speed while both strings remain tight. If the tension $T_{1}$ in the upper string is measured to be 80 N , what is the tension $T_{2}$ in the lower string? How many revolutions per minute does the system make?

(b) [2 pt] A stunt car is driven at constant speed over a hill and then into a valley (see figure). The crest of the hill and the trough of the valley are both approximated by a circle of the same radius $R=20 \mathrm{~m}$. What is the maximum speed that the car could have at the top of the hill to remain in contact with it there? What is the normal force on the driver ( $m=60 \mathrm{~kg}$ ) from the car seat there? Assuming that the car is driven at this speed since then, what is the normal force on the driver from the seat when the car passes through the bottom of the valley? To realize the motion discussed here, what does the driver need to do as the car descends from the top of the hill into the valley (i.e., can he simply do nothing with his foot off the brake or the gas pedal)?

3. A ballistic pendulum consists of a block of wood of mass $M_{1}=4.0 \mathrm{~kg}$ hanging from a hinged rod that can swing without friction on the horizontal axle (point A).
(a) [ 1 pt$]$ Let us for the time being assume that the hinged rod is massless. A bullet of mass $m=15 \mathrm{~g}$ is fired into the block with an unknown constant speed $v$, coming quickly to rest inside the block. The collision is so brief that we can assume that the block+bullet system is isolated during the collision, and the collision is 1-dimensional. Immediately after the collision, the block - with the bullet at its center - begins to swing upward (see figure). Their center of mass (CoM) rises a vertical distance $h=6.0 \mathrm{~cm}$ before the pendulum comes to rest momentarily. Determine $v$ using the numerical values given herein.

(b) [1 pt] During the block's ascent to $h$ right after the collision, (i) how much work is done on the block+bullet system by the gravitational force? (Note: You are asked to explicitly evaluate the amount of work using $W=\vec{F} \cdot \vec{d}$ where $\vec{d}$ is the displacement of the CoM noted in the figure. Here we assumed that $\alpha$ and $h$ are so small that the arc along which the CoM moves can be approximated as a straight vector $\vec{d}$.) Using your result, (ii) show that the negative of the work done on the block by the gravitational force is the change in its gravitational potential energy, $\Delta U$.
(c) $[1 \mathrm{pt}]$ During the block's ascent to $h$ right after the collision, show that the net work done on the block is the change in its kinetic energy, $\Delta K$. Why do you not need to consider the work done on the block+bullet system by the force of the rod?
(d) [2 pt] Now let us abandon the assumption that the hinged rod is massless, and re-estimate the bullet's speed $v$. Assume that the uniform thin rod has mass $M_{2}=1.0 \mathrm{~kg}$ and length $l=60$ cm , while the block $M_{1}$ can be treated as a particle (i.e., the size of the block is small compared to $l$ ). (i) Then, what is the rotational inertia of the block + bullet + rod system about point A? (ii) If the angular speed of the block+bullet+rod system about point A immediately after the collision is measured to be $1.6 \mathrm{rad} / \mathrm{s}$, determine $v$ using the numerical values given herein. (Note: The table of various rotational inertias is in the last page of this exam.)
4. (a) [2 pt] A spacecraft of mass $m_{1}=9,500 \mathrm{~kg}$ and speed $v_{1 i}=9.9 \mathrm{~km} / \mathrm{s}$ approaches Jupiter of mass $m_{2}=1.9 \times 10^{27} \mathrm{~kg}$ and speed $V_{J}=13 \mathrm{~km} / \mathrm{s}$. The two velocities are relative to the Sun, and are in opposite directions (see figure). The spacecraft then rounds the planet, and departs
with speed $v_{1 f}$ (relative to the Sun) in the opposite direction. What is the magnitude of $v_{1 f}$ after this slingshot encounter which can be approximated as an elastic collision?

(b) [2 pt] When suspended from a coil spring of negligible mass, a steel plate of mass $m_{1}=150 \mathrm{~g}$ (with frames of negligible mass) stretches the spring by $d_{0}=15 \mathrm{~cm}$. Then, a lump of sticky clay of mass $m_{2}=200 \mathrm{~g}$ is dropped from rest onto the plate from a height of $h=30 \mathrm{~cm}$ (see figure). Find the maximum distance $d$ the plate travels downward from its initial equilibrium position.

5. (a) [2 pt] Using integration, calculate the moment of inertia of each of the following objects about its axis of symmetry (see figure): (i) an annular cylinder of mass $M$ and uniform density with height $h$, inner radius $R_{1}$, and outer radius $R_{2}$, (ii) a solid cone of mass $M$ and uniform density with height $h$, and the radius of its circular base $R$. (Note: For (i), you may already find the answer in the table of rotational inertias in the last page of this exam. For (ii), you may want to utilize the rotational inertia of a uniform disk listed in the same table.)

(b) [2 pt] A rigid assembly of a thin hoop (of mass $m=1.0 \mathrm{~kg}$ and radius $R=15 \mathrm{~cm}$ ) and a thin rod (of mass $m$ and length $2 R$ ) is positioned upright (see figure). It can rotate around a horizontal, frictionless axle which is in the plane of the hoop, through the lower end of the $\operatorname{rod}($ point $A)$. Now, in order to initiate a rotation, a constant force $\vec{F}=49 \mathrm{~N}(=5 \mathrm{mg})$ is exerted on the top end of the hoop (point B) perpendicular to the hoop's plane at all times, while the assembly rotates by $\Delta \theta=0.1 \mathrm{rad}$. What are the magnitudes of the assembly's angular velocity $\vec{\omega}$ and angular momentum $\vec{L}$ about the rotation axis when it passes through the inverted (upside-down) orientation? (Note: The table of various rotational inertias is in the last page of this exam.)

## (i) face-on view <br> (ii) edge-on view

6. (a) [2 pt] A thin-walled, hollow spherical shell of mass $m$ starts from rest and rolls smoothly without slipping down a track (see figure). The diameter of the shell, $2 r$, is very small compared to the radius of the circular loop, $R$. The work done by rolling friction is negligible. (i) What is the shell's initial height $h$ (in units of $R$ ) for which this shell will be on the verge of leaving the track when reaching the top of the loop (point A)? (ii) In this case, how hard does the track push on the shell (in units of $m g$ ) at point A ? How about at point B , which is at the same level as the center of the circle? What is the direction of this force acting on the shell at each point?

Now, suppose that the track had no friction and the shell was released from the same height $h$ you found above. (iii) Would it make a complete loop-the-loop on the circular part of the
track? How do you know without even explicitly calculating the numerical values? (iv) In this case, how hard would the track push on the shell (in units of $m g$ ) at point A and at point B, respectively? (Note: The table of various rotational inertias is in the last page of this exam.)
(b) [2 pt] A titanium wheel of mass $m=5.0 \mathrm{~kg}$ and radius $R=20 \mathrm{~cm}$ is resting against a step of height $h=10 \mathrm{~cm}$. (i) A horizontal force $\vec{F}$ is applied at the axle of the wheel to roll it over the step obstacle (see figure). What is the minimum force magnitude necessary? (Note: As the magnitude of $\vec{F}$ increases, there comes a moment when the wheel begins to rise up and loses contact with the ground.) (ii) Now, in a different scenario, a constant force $\vec{F}$ is applied at the axle of the wheel at angle $\theta$ above the horizontal, just enough to start lifting the wheel off the ground (see figure). What is the value of $\theta$ that requires the least magnitude of the force $\vec{F}$ ? At this angle $\theta$ you just found, what is the magnitude of $\vec{F}$ ?

(ii)

Table 10-2 Some Rotational Inertias
